This paper uses machine learning to analyze text based on cisgender subjects in the reality television series *Love Is Blind* (2020-present). From the transcripts of the show, I train small-scale language models (SLMs) and use them as predictive instruments to surface shared linguistic and affective patterns among the show participants. The experiment finds that these participants, while firmly anchored in cisnormative frameworks, temporarily experience a form of bodily dissonance and disjunction that evokes the language of body dysphoria from trans studies. The paper ultimately argues that machine learning, as an aggregative mechanism, ought to be used as a tool for studying common and shared experiences in language, such as experiences of bodily disjunction and attachments to normativity, in the case of the *Love is Blind* participants.
